

Lifespans of Australian Prime Ministers

Brooklin Becker

February 28, 2024

Figure 1: Graph shows the span of the time period in which each prime minister lived, with the bars for currently living prime ministers stopped at the current year.

Findings

Shown in the graph on the first page is a visual representation of the lifespan of each of Australia's prime ministers since the Australian parliament's inception in 1901. The time period from 1901 to present spans 123 years, in which 31 prime ministers assumed office. Out of the country's 31 prime ministers, 8 are still living, in which all 8 are also the most recent prime ministers - office-holding prime minister included.

As expected, there is some variation in the years lived of prime ministers, as the red bars are of different lengths for different prime ministers that passed away. Below is a table summarizing the minimum, maximum, and average years lived for deceased prime ministers. There is no name for the average, so a placeholder of "NA" is used.

The average of all years lived of deceased prime ministers is essentially halfway between the two ends of the range of years lived, namely the minimum and maximum values. This shows that at first glance, without showing the entire distribution of years lived, the data appears to be fairly symmetric about the mean. If we wanted to make a prediction as to how long the 8 currently living prime ministers will live to, we would take the average of 78 years, and subtract it from their current age which is just the current year minus their birth year. This of course wouldn't be applicable to those prime ministers that are already past 78, namely Paul Keating and John Howard.

Metric	Name	Age
Minimum Age	Harold Holt	59
Maximum Age	Gough Whitlam	98
Average Age	NA	78

Data Source

I scraped Wikipedia to gather this data, particularly from the Wiki page entitled *List of prime ministers of Australia* (Contributors, n.d.). I took a similar approach as used in the example for the United Kingdom's prime ministers, however I ran into some trouble fairly quickly. In the data from the table that was gathered, some of the columns had different names compared to the example, and also the formatting differed from the example particularly in how the name, birth, death, and constituency was listed for each prime minister. This meant that some of the code had to be altered, which took longer than expected to identify because the difference in formatting for currently living prime ministers was quite minute, i.e. in the UK example it is written (born Year) and in the Australian table it is written (b. Year).

It started to become more fun for me once I figured out the few code changes that needed to be made, as several of the R chunks after that point remained the same and I was able to clean the data effectively to create the new columns of the birth year, death year, and age at death for each deceased prime minister, and adjust accordingly for the 8 prime ministers still

living. I like the idea of being able to scrape data from sites with data tables that have lots of unneeded noise that I can filter out and clean, in order to visualize the selected data in a different way such as the graph shown in this paper.

The next time that I do this, I would like to keep more columns as part of the cleaned data being analyzed, as that will allow me to make more graphs and comparisons with the data. For data on prime ministers/presidents of countries, I would keep the columns listing the political parties, and perhaps also the time in office, as those could make for interesting visualizations through graphs.
